## ARC-52 Radio

Back to [General and Technical Information](#).

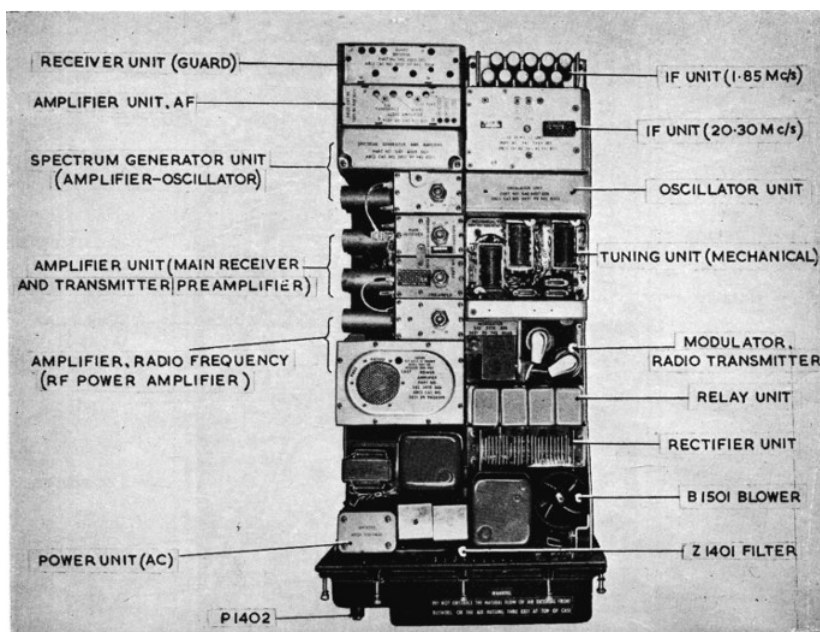

Recently, I've had a few requests for help with these aircraft radios, so thought I'd start sharing some technical information about the ARC-52 radio itself and how it integrates with aircraft.

### What is an ARC-52 Radio?

It's a beautifully engineered Cold-War era UHF communications radio, used in a lot of RAF aircraft from the 1960's to the early 1990's, and some are still flying privately today.

The technology is electro-mechanical, and is based on: thermionic valves; crystals; variable capacitors; rotary inverter power supply; and carbon-pile voltage regulators. Re-tuning is via a wonderful mechanical clunking, whirring function of gears and motors, introducing different crystals into circuit, and re-tuning variable capacitors.

It weighs a ton and produces, at best, about 5 Watts of AM RF.

Main ARC-52 Transmitter / Receiver (TR) Unit

Cockpit panel mounted Control Unit

## Frequency Range

100KHz channel spacing, frequency ranges as below:

### UHF:

225.00 to 399.9Mhz

1750 channels

## System

On it's own, the main Transmit / Receive Unit (T/R Unit) isn't of much use, as it relies upon some other key components to build up a system to integrate with an aircraft:

- T/R (Transmitter / Receiver) unit.
- Control unit.
- Interconnecting Box (or other interconnecting means).
- Antennae and associated selectors and cabling.
- Interfacing cabling and connectors for power, mic / tel, panel lighting etc..
- Integration with navigation equipment.
- In a a multi-seat aircraft, integration with an intercom system.

Typically a whole aircraft radio system would also include a standby radio, and emergency power supplies for either radio. Also included would be other audio signals from navigation and warning equipment.
